Herbarium, Botanical Research Center, P.O. Box 6717, Bryan, TX 77805-6717

ABSTRACT. This poorly understood and confusing group is centered around Cyperus retroflexus, until recently known as C. uniflorus. Typification of C. uniflorus var. pumilus is discussed, and the following new combination is made: C. retroflexus var. pumilus. Two varieties of C. uniflorus are discussed and elevated to species: C. floribundus and C. pseudothyrsiflorus. Included is a dichotomous key treating the aforementioned taxa and putative allies of C. pseudothyrsiflorus: C. hermaphroditus, C. lentiginosus, C. tenuis, and C. thyrsiflorus.

Key Words: Cyperaceae, Cyperus section Umbellati, C. floribundus, C. pseudothyrsiflorus, C. retroflexus var. retroflexus, C. retroflexus var. pumilus, C. uniflorus

Revisional studies in Cyperus section Umbellati (Carter 1984; Carter, in prep.) and preparation of treatments of the genus for Flora of North America and Vascular Plants of Texas by Jones, Wipff, and Montgomery (1997) have brought to light several taxonomic and nomenclatural problems bearing heavily on the Texas flora. These problems involve the species formerly known as C. uniflorus Torr. & Hook., now properly known as C. retroflexus Buckley (Tucker 1987, 1994). Fernald and Griscom (1935) wrote that the "supposed new species" C. uniflorus was based on an immature specimen of C. strigosus L., evidence that the taxon has long been problematic. Although we concur with Fernald and Griscom that type material (Drummond 287) of C. uniflorus is immature, we disagree, as did Kükenthal (1936) and others (Horvat 1941; O'Neill 1942), that the type belongs in C. strigosus. Kükenthal, in a comprehensive monograph of the genus, treated this complex as five taxa shown in Table 1. Horvat subsequently placed all of these names into synonymy under C. uniflorus, a

view essentially upheld by O'Neill. Tucker (1994) followed Horvat and O'Neill in recognizing but a single taxon, albeit under *C. retroflexus*. Table 1 compares these various taxonomies and ours.

RESULTS AND DISCUSSION

Our field and herbarium studies support Kükenthal's contention that multiple taxa are involved; however, as shown in Table 1, in departure from Kükenthal, we recognize three species and one variety. Our revised taxonomy is based upon combinations of vegetative, spike, spikelet, scale, and achene characters, some previously unused, which are summarized in key form and in Tables 2, 3, and 4. Moreover, discovery that Cyperus uniflorus Torr. & Hook. is illegitimate (Tucker 1987, 1994) complicates the problem somewhat, especially since we have determined, as did Horvat (1941), that the type of C. uniflorus Torr. & Hook. is not the same as C. retroflexus, but instead is an immature specimen of C. uniflorus var. floribundus, which we treat as a distinct species. All of this necessitates revision of the taxonomy and nomenclature of this complex. Thus, we propose: C. retroflexus var. pumilus (Britton) R. Carter & S. D. Jones, comb. nov.; C. floribundus (Kük.) R. Carter & S. D. Jones, stat. nov.; and C. pseudothyrsiflorus (Kük.) R. Carter & S. D. Jones, stat. nov.

Typification of Cyperus uniflorus var. pumilus Britton. Britton (1884) described Cyperus uniflorus var. pumilus, based primarily upon an S. B. Buckley collection from the "Valley of the Lower Rio Grande, in Texas and Northern Mexico." Subsequently, Small (1903) elevated this taxon to species rank and, crediting Britton with authorship, called it "Cyperus subuniflorus Britton," citing in synonymy "C. uniformis [sic] var. pumilus Britton, not C. pumilus L." Kükenthal (1936), like Small, treated C. subuniflorus as a distinct species allied with C. uniflorus. Apparently unaware of Britton's 1884 publication of var. pumilus, Horvat (1941) and O'Neill (1942) mistook an entry in a list published by Britton two years later (1886) as a nomen nudum. In fact, Britton in 1884 had provided a description with the name and thus had validly published it under Articles 32 & 36 of the ICBN (Greuter et al. 1994).

As was usually the case then, Britton (1884) did not explicitly designate in publication a holotype for Cyperus uniflorus var.

Table 1. Comparison of taxonomic treatments of the Cyperus retroflexus complex.

Present Treatment 4 Taxa	Kükenthal (1936) 5 Taxa	Horvat (1941) O'Neill (1942) 1 Taxon	Tucker (1994) 1 Taxon
C. floribundus	C. uniflorus var. uniflo- rus	C. uniflorus	C. retroflexus
	C. uniflorus var. flori- bundus		
C. pseudothyrsiflorus	C. uniflorus var. pseudo- thyrsiflorus		
C. retroflexus var. retroflexus	C. uniflorus var. retro- flexus		
C. retroflexus var. pumilus	C. subuniflo- rus		

pumilus. However, the title of his article "A list of Cyperaceae collected by the late Mr. S. B. Buckley from 1878 to 1883 in the valley of the lower Rio Grande, in Texas and northern Mexico" obviously indicated that a Buckley collection was the basis for C. uniflorus var. pumilus. At NY, there are two sheets of Buckley collections from the valley of the Lower Rio Grande, dated 1878–1883. On virtually identical labels, handwritten by N. L. Britton, these specimens are identified as "Cyperus uniflorus, Torr.; var. pumilus, Britton." The only substantive difference between the two labels is that one bears the additional designation "type."

It would seem that the NY specimen marked "type" should be recognized as holotype. However, in addition to his obvious reference to Buckley's collections, Britton (1884) cited another collection as follows: "I refer here also No. 350, Palmer, Indian Territory." Specimens of *Palmer 350* are at NY and US. Although no Buckley collections were cited beyond the title, the new taxa described by Britton, including *Cyperus uniflorus* var. *pumilus*, were obviously based upon collections of S. B. Buckley, and only secondarily were other specimens such as *Palmer 350* cited. Unfortunately, Horvat (1941) and O'Neill (1942) stated "*Palmer 350* from the Indian Territory and Buckley's specimen from the valley of the Lower Rio Grande (1879–1883) are respectively the

	C. retroflexus var. retroflexus	C. retroflexus var. pumilus
Plant height	Except for depauperate specimens, plants usually greater than 25 cm tall	Plants diminutive, 3-35 (-45) cm tall
Length longest peduncle Fertile floral scale length	-	Longest peduncle less than 2.7 (-3.9) cm long Fertile floral scales 1.9-3.0 (-3.3) mm long
Terminal floral scale	Terminal sterile floral scale usually not greatly reduced, 2/3 or more the length of fertile scales	Terminal sterile floral scale of spikelet often much reduced, then less than 2/3 the length of fertile
Rachilla nerves	Rachilla usually with two conspicuous nerves, one on either side of median	nerves, one Rachilla usually without conspicuous nerves
Rachilla wing texture	Rachilla wing usually chartaceous beyond clasped achene angle, border membranaceous (rarely wing almost entirely membranous)	Rachilla wing membranaceous throughout (rarely medially chartaceous)
Spikelet length	Longest spikelets 4.9-9.0 (-11.3) mm long	Longest spikelets 2.8-5.8 (-8.0) mm long

	C. floribundus	C. retroflexus var. retroflexus
Spikelet length Spikelet outline	Longest spikelets (9.0-) 9.8-21.25 mm long Spikelets strongly flexuous-contorted	Longest spikelets 2.8–9.0 mm long Spikelets not strongly contorted, at most flexuous with curved tips
Spikelet base	Spikelet base strongly stipitate, 0.4-1.0 mm long	Spikelet estipitate or only weakly stipitate and stipe 0.1–0.3 (–0.5) mm long
Length longest floral scale	(3.5-) 3.7-4.8 mm	(2.8-) 3.0-3.9 mm
rioral scarc color	or pale whitish	Fale whitish or reddish brown, less commonly sanguineous, usually reddish brown maculate
Floral scale apex	Distal fertile floral scales with prominent mucro 0.6-1.9 mm long	Distal fertile floral scales obtuse to acute or with short mucro 0.1-0.3 (-0.5) mm long
Floral scale keel	Keel of distal fertile floral scales usually scabrid (30× magnification)	
Anther length Achene length: width ratio Distribution	0.5–1.3 mm Achenes more than 3 times as long as wide Plants restricted to lower Rio Grande valley and adjacent areas of southern Texas and northeast- ern Mexico, with outlier in Travis County, Texas	0.3–0.5 (–0.6) mm Achenes 2–3 (–3.3) times as long as wide Plants more widely distributed, throughout northern Mexico and Texas westward into New Mexico, northward into Oklahoma and southeastern Missouri, and eastward through Arkansas and northern Louisiana with outliers in western Kentucky, Mississippi, and eastern Alabama

	C. pseudothyrsiflorus	C. thyrsifforus	C. tenuis	C. lentiginosus	C. hermaphroditus
Mid-culm diameter	2.0-2.6 mm	0.5-1.1 mm	1.2-2.2 mm	(0.8-) 1.1-3.0 mm	(1.3-) 2.0-3.6 mm

type and cotype" Furthermore, O'Neill annotated as "TYPE" a duplicate of *Palmer 350* (US). Although *Palmer 350* (US) was annotated by Britton as *C. uniflorus* var. *pumilus*, we think it is significant that Britton in no way indicated it was a type. Duplicates of *Palmer 350* (NY, US) examined by us are very immature, and although the plants are diminutive, as would be expected with *C. uniflorus* var. *pumilus*, their yet immature fertile scales are already 2.9–3.2 mm long, which is at the taxon's upper limit as understood by us. In contrast, the Buckley specimens (NY) are more mature, have shorter [2.4–2.5 (–2.8) mm long] scales, and are generally more representative of the taxon. Thus, we reject the Horvat (1941) and O'Neill (1942) designations of *Palmer 350* as "type" and the *Buckley* specimen as "co-type" and think the Buckley specimen at NY, annotated by Britton as "type," should stand as holotype.

Cyperus retroflexus var. pumilus, comb. nov. [=C. uniflorus var. pumilus; C. subuniflorus]. Fernald and Griscom (1935) asserted that this taxon "is merely small individuals of C. globulosus." However, we think this taxon is a distinct variety and find no evidence that it is related to C. globulosus auct. non Aubl., now properly known as C. croceus Vahl (Carter and Kral 1990). Small (1903) and Kükenthal (1936) recognized this taxon as a distinct species (C. subuniflorus) allied with C. uniflorus. Horvat (1941) and O'Neill (1942) treated it as a synonym of C. uniflorus, commenting that "it is impossible to draw any kind of dividing line between [C. uniflorus and C. subuniflorus] . . . when a large number of specimens are studied" and further that "[C. uniflorus and C. subuniflorus] appear to stand at opposite ends of a long series of intergrading forms." We concur with Horvat and O'Neill that these taxa do not merit species rank. As shown in Table 2, there is overlap in virtually every characteristic we examined in C. retroflexus var. retroflexus [=C. uniflorus, sensu Horvat andsensu O'Neill] and C. retroflexus var. pumilus [=C. subuniflorus]. Despite this, we find that most specimens may be reliably placed in var. retroflexus or var. pumilus when combinations of characteristics are used, and given the disparate nature between specimens at opposite extremes of this continuum, we think infraspecific rank is both logical and useful. In the absence of evidence of geographical or habitat isolation, we maintain C. uniflorus var. pumilus at varietal rank but transfer it to C. retroflexus. Differences between *C. retroflexus* var. *retroflexus* and *C. retroflexus* var. *pumilus* are summarized in Table 2 and in the accompanying key.

Cyperus floribundus, stat. nov. [=C. uniflorus var. floribundus]. Kükenthal (1936) described Cyperus uniflorus var. floribundus based upon its relatively loose spikes, longer 3–5 fruited spikelets, and distal scales with long recurved mucros. Subsequently, the taxon was placed in synonymy under C. uniflorus (Horvat 1941; O'Neill 1942) and C. retroflexus (Tucker 1994). We concur with Horvat and with O'Neill that C. uniflorus var. floribundus is the same as C. uniflorus Torr. & Hook. and with Tucker (1987, 1994) that C. uniflorus Torr. & Hook. 1836 is illegitimate (non C. uniflorus Thunb. 1825), requiring use of C. retroflexus, the next available name.

We also concur with Horvat and with O'Neill that Kükenthal's brief diagnosis of Cyperus uniflorus var. retroflexus as having culms 45-75 cm high and terete, reflexed spikelets is insufficient to allow its separation from the rest of the complex. However, we find numerous characteristics to distinguish C. floribundus from C. retroflexus (summarized in Table 3) and do not agree with Horvat (1941), O'Neill (1942), and Tucker (1994), who have placed C. uniflorus var. floribundus into synonymy under C. uniflorus and C. retroflexus. Both C. floribundus and C. retroflexus var. retroflexus exhibit bewildering variation in habit from low slender plants to more robust ones of moderate stature; therefore, in our circumscription we use spikelet, scale, and achene characters almost exclusively. Moreover, although C. retroflexus and C. floribundus are sympatric, the distribution of C. floribundus appears to have integrity as a rather tight cluster of populations in southeastern Texas and adjacent northeastern Mexico, nested entirely within the range of C. retroflexus. Thus, we propose recognition of C. floribundus as a distinct species.

Cyperus pseudothyrsiflorus, stat. nov. [=C. uniflorus var. pseudothyrsiflorus]. Cyperus uniflorus var. pseudothyrsiflorus Kük. was treated as a synonym of C. retroflexus by Tucker (1994). Horvat (1941) wrote "[o]f doubtful status is C. uniflorus pseudothyrsiflorus Kükenth. [=Mariscus dissitiflorus C. B. Clarke]" and she further speculated "[t]hese plants may possibly be hybrids of C. uniflorus and C. setigerus." These views were

echoed by O'Neill (1942). We can find no morphological evidence that *C. pseudothyrsiflorus* is a hybrid between *C. uniflorus* and *C. setigerus* Torr. & Hook., and we think such a hybrid is unlikely given the genetic disparity between the putative parents; *C. setigerus* is a member of section *Rotundi* (with *C. rotundus* L.) and is not even remotely related to *C. uniflorus*. Curiously, despite erroneous speculation with regard to hybrid origin, Horvat (1941) and O'Neill (1942) did observe a relationship between *C. uniflorus* var. *pseudothyrsiflorus* and *Mariscus dissitiflorus* [=*C. thyrsiflorus* Jungh.], with which we concur. Also, in choosing the epithet *pseudothyrsiflorus*, Kükenthal (1936) obviously saw some resemblance, although to him presumably superficial, with *C. thyrsiflorus*.

Although Cyperus sections are ill-defined and poorly understood and its sectional taxonomy is sorely in need of revision, we think C. pseudothyrsiflorus is more closely allied with C. thyrsiflorus [=Mariscus dissitiflorus], C. tenuis Sw., C. lentiginosus Millsp. & Chase, and C. hermaphroditus (Jacq.) Standl. than with C. retroflexus (C. uniflorus as previously treated). Also, Correll and Johnston (1970, p. 298) suggested a relationship between var. pseudothyrsiflorus and C. hermaphroditus. However, this putative alliance contains members of three sections (see Table 5) as understood by Kükenthal (1936), and additional study is needed before a formal proposal to realign the sections can be made. Herein, we propose species rank for C. uniflorus var. pseudothyrsiflorus and provide a dichotomous key to allow its separation from C. retroflexus and C. floribundus and from its putative allies: C. thyrsiflorus, C. tenuis, C. lentiginosus, and C. hermaphroditus. Species in this putative alliance are further compared in Table 4.

REVISED TAXONOMY

1. Cyperus retroflexus Buckley, Proc. Acad. Nat. Sci. Philadelphia. 1862: 9. 1863.

Cyperus uniflorus var. retroflexus (Buckley) Kük., Pflanzenreich IV. 20 (101): 521. 1936. Type: U.S.A. Texas: northern Texas, S. B. Buckley s. n. (LECTOTYPE designated here: PH!).

KEY TO CYPERUS RETROFLEXUS AND ALLIES

- - Longest spikelets 9.8–21.25 mm long, strongly flexuous-contorted; spikelet with strongly stipitate base 0.4–1.0 mm long; achenes more than 3 times as long as wide; distal fertile floral scales with prominent mucro 0.6–1.9 mm long; longest floral scale of spikelet (3.5–) 3.7–4.8

- - 3. Fertile floral scales (2.8–) 3.0–3.9 mm long; rachilla wing usually chartaceous beyond clasped achene angle, border membranaceous; rachilla usually with two lateral nerves, one along each side of median; longest spikelets 4.9–9.0 (–11.3) mm long; terminal sterile floral scale usually not greatly reduced, ½ or more the length of fertile floral scales; longest peduncle (0.5–) 2.4–6.8 cm long; except for depauperate specimens, plants usually greater than 25 (–57) cm tall C. retroflexus var. retroflexus
- 1. Floral scales on same side of spikelet mostly overlapping or at least reaching base of next floral scale (best observed in mature spikelets); achenes 1.4–1.9 (–2.1) mm long; at least ½ of ventral achene edge extending beyond rachilla wing (free portion of achene measured from intersection of rachilla edge and achene ventral edge to achene apex); lower bracteoles in pedunculate spikes mostly narrowly

	triangular to linear-triangular and setaceous, longer than associated secondary prophylls (except in C. thyrsiflorus).
4.	Spikelets remote, 6–10 (–15) per 5 mm rachis span in proximal half of rachis
	5. Distal floral scales mucronate, mucros 0.2–0.5 mm long;
	scales (2.9-) 3.3-4.0 mm long; spikelets stipitate,
	stipes 0.3–0.5 mm long; scales mostly about 2×
	[(1.61-) 1.72-2.55] as long as achenes; spikelets
	8.9-11 mm long; lower bracteoles in pedunculate
	spikes mostly narrowly triangular to linear-triangu-
	lar and setaceous, longer than associated secondary
	prophylls; largest leaves and primary inflorescence
	bracts usually more than 3.0 mm wide; largest pe-
	duncles usually more than (0.4-) 0.5 mm wide; ma-
	ture achene light brown with distinctly darker base
	and apex; floral scales chestnut to cinnamon brown
	sometimes yellow tinted C. lentiginosus
	5. Distal floral scales without mucros or mucros 0.1 mm
	or less long; floral scales 2.0-2.8 (-3.0) mm long;
	spikelets estipitate or stipes no more than 0.2 mm
	long; floral scales mostly about 1.5× [1.31–1.75
	(-1.88)] as long as achenes; spikelets 3.4-7.4 (-17)
	mm long; lower bracteoles in pedunculate spikes
	mostly triangular to narrowly triangular and no lon-
	ger than associated secondary prophylls; largest
	leaves and primary inflorescence bracts 1.0–2.8
	(-3.0) mm wide; largest peduncles 0.2-0.5 (-0.55)
	mm wide; mature achene dark brown throughout;
	floral scales whitish along nerves and margins, with
	chocolate to liver brown undercolor mostly between
1	nerves C. thyrsiflorus
7.	Spikelets more congested, (9-) 11-45 per 5 mm span in
	distal half of rachis
	6. Distal floral scales mucronate, mucros 0.2-0.5 mm long;
	floral scales predominately reddish, brownish, or
	whitish; rachis, spikelets, bracteoles, and prophylls
	usually conspicuously reddish brown maculate or
	striate (10× magnification)
	7. Spikes loose, 8-12 spikelets per 5 mm span of upper
	half of rachis; floral scales (2.9-) 3.3-4.0 mm

- 6. Floral scale mucro absent or if present then less than 0.1 mm long; floral scales golden yellow to stramineous (to red-brown) or pale olivaceous with chocolate to liver brown undercolor; rachis, spikelets, bracteoles, and prophylls not conspicuously maculate or striate (10× magnification) (8)
